(Dated: October 23, 2012)

We use non-linear gauge-invariant perturbation theory to study the interaction of an inflation produced seed magnetic field with density and gravitational wave perturbations in an almost Friedmann-Lemaître-Robertson-Walker (FLRW) spacetime with zero spatial curvature. We compare the effects of this coupling under the assumptions of poor conductivity, perfect conductivity and the case where the electric field is sourced via the coupling of velocity perturbations to the seed field in the ideal magnetohydrodynamic (MHD) regime, thus generalizing, improving on and correcting previous results. We solve our equations for long wavelength limits and numerically integrate the resulting equations to generate power spectra for the electromagnetic field variables, showing where the modes cross the horizon. We find that the interaction can seed Electric fields with non-zero curl and that the curl of the electric field dominates the power spectrum on small scales, in agreement with previous arguments.

I. INTRODUCTION

Large scale magnetic fields of varying amplitudes are present in entire galaxy clusters, individual galaxies and high redshift condensations. Such fields are observed on characteristic scales of $\sim 1$ Mpc and are of micro-Gauss strength, $10^{-7} - 10^{-5}$ G [1, 2]. Despite their ubiquity, their origin is still a mystery. There are literally tens of candidate mechanisms proposed to explain the origin and evolution of such fields, spanning different theories of physics [3]. It is now widely believed that the structure of magnetic fields in spiral galaxies is consistent with the dynamo amplification mechanism. The dynamo mechanism can produce amplification factors of up to $\sim 10^8$ but requires a seed field in order to operate and thus cannot explain the origin of magnetic fields. Additionally, adiabatic contraction of magnetic flux lines during structure formation can enhance galactic fields by a factor of $\sim 10^3$.

Among the physical mechanisms proposed to explain the origin of the seed field is one due to Harrison [4]. This mechanism rests on the fact that non-zero vorticity in the pre-recombination photon-baryon plasma can generate weak magnetic fields of about $\sim 10^{-25}$ G. However, vorticity is not a generated mode at first order in perturbation theory and has to be put in as an initial condition. Second order treatments of the pre-recombination plasma in terms of a Kinetic theory description has also been used to generate the required seed fields [5–10]. The key idea is a preferential Thompson scattering of photons off free electrons, over the scattering off protons (the scattering off protons is suppressed by a factor $(m_e/m_p)^2$) which induces differences in the proton and electron velocity fields. Electric fields are then induced to counter charge separation between the electrons and protons. The generated electric fields will then feed in the magnetic induction equation to generate magnetic fields at second order in perturbation theory. The photon anisotropic stress also couples to the electron velocities and contributes to the magnetic field sources. In addition, other arguments relying on electroweak phase transitions [11, 12], topological defects [13], velocity perturbations etc. have been proposed as candidate mechanisms. The generated fields, however, are usually too weak to leave any detectable imprint on the CMB [3]. This is not surprising given the form of the fluid quantities of a magnetic field. In particular, the energy density $\mu_B = B^2/2$, the isotropic pressure $p_B = B^2/6$ and the anisotropic pressure $\Pi_{ab} = \langle B_a B_b \rangle$ of a field generated at second order will manifest at fourth order in perturbation theory, which is not relevant for CMB anisotropies.

In addition to meeting the right strengths, the generated fields must be of the right scale to match those observed today. One of the problems of primordial generation mechanisms in general is that although some may reach the required strengths, they are causal in nature. This means that their coherence scales cannot exceed the Hubble scale.

during the time of magnetic field generation. By comparison, the galactic scale today is well outside the Hubble scale at such early epochs. Moreover, the small scale fields i.e., those that are already sub-horizon before matter-radiation equality cannot reach the recombination epoch due to micro-physical mechanisms such as magnetic and photon diffusion processes [3].

Inflation and other pre-Big Bang models capable of causally producing super horizon perturbations are often invoked to circumvent this scale problem. However, the residual magnetic fields surviving the exponential expansion accompanying many inflationary models are thought to be too weak to be of cosmological relevance [17]. New physics often has to be introduced such as exotic couplings of the electromagnetic field to other fields such as the dilaton field to avoid the accompanying exponential dilution of the magnetic fields [15]. The primordial fields are also constrained by the fact that the anisotropic stress of the produced magnetic fields contains a spin-2 component and will result in an overproduction of gravitational waves at horizon crossing which is inconsistent with standard Big Bang Nucleosynthesis constraints [16, 17].

Apart from studying the generation of magnetic fields, one can also study interactions of a pre-existing magnetic field with gravitational degrees of freedom. This is often studied in the context of amplification of the seed magnetic field or gravitational wave detection. Much progress has been made in this area [18, 21]. Most of these studies however have been restricted to focusing on the interaction of magnetic fields with tensor perturbations; In this work we revisit and extend the work presented in [18, 21, 22], to include scalar perturbations in the matter fluctuations.

When using perturbation theory about a FLRW background to study the interaction, one is immediately faced with the problem of how to embed the seed magnetic field into the background. The isotropy of the FLRW spacetime does not readily allow for any direction preference that may be introduced by a vector field. There are several ways to handle this and we mention briefly just three of them. One can treat the seed magnetic field as a zeroth order quantity, subject to the assumption that the energy density of the field be small compared to the energy density of matter $B^2 \ll \mu$ and that the anisotropic stress is negligible $\Pi_{ab} = B_{(a} B_{b)} \approx 0$. With these approximations, the energy density of the magnetic field cannot alter the gravitational dynamics of the background spacetime; this approach is often referred to as the weak-field approximation. Another approach is to treat the seed field as a statistically homogeneous and isotropic random field with $\langle B \rangle = 0$ but $\langle B^2 \rangle \neq 0$ and so, the seed field does not introduce any directional dependence in the background spacetime. One can then easily employ statistical methods to quantify the field’s behavior. Another possibility is to leave the background spacetime untouched but treat the seed field as a first order perturbation, using a two parameter approximation scheme to characterize the perturbations in the electromagnetic and gravitational field; this is the approach we adopt in this work.

One can go a long way in comparing the different perturbation schemes. For example, in the weak-field approximation, the induced magnetic field will be at first order, a well understood regime in perturbation theory. While in the two parameter case, the induced field will be at second order [66], a regime that is not so well developed. Nevertheless, for the purposes of our work, the two approaches are mathematically equivalent. The apparent differences between them is as a result of relabeling of spacetimes, i.e. ‘First order’ in the weak-field approximation corresponds to ‘second order’ in the two parameter case. Indeed, Maxwell’s equations and thus the Einstein-Maxwell system takes the same mathematical form in both of these approaches. They both use the machinery of relativistic perturbation theory and are thus prone to gauge issues, see [23, 24] for example.

The present article is structured as follows: we present details of our perturbative framework in § III. After a presentation of the interaction equations in § VI, we present the derivation of the equations describing the induction of EM fields in § VII A and VII B for a general current and a note on how to evaluate the induced electrical current in VII C. We present the power spectra of the induced magnetic field variable in § VIII and finally a summary in XI. We employ the 1+3 covariant approach to perturbation theory [27] and follow [28] by adopting the more geometrically motivated metric signature $(- + + +)$ and we use geometrized units $8\pi G = c = 1$, where $G$ is the gravitational constant and $c$ is the speed of light in vacuum.

II. PRELIMINARIES

A. 1+3 spacetime splitting

One of the nice aspects of the 1+3 covariant approach to General Relativity (GR) is that the underlying dynamical equations have a stronger appeal from a physical point of view, as compared to the quasi-linear, second-order partial differential equation form, which the EFE take in the metric based approach.

The approach is based on a 1+3 decomposition of geometric quantities with respect to a fundamental four velocity $u^a$.

$$u_a = \frac{dx^a}{d\tau}, \quad u_a u^a = -1,$$  \hspace{1cm} (1)
where \( x^a \) are general coordinates and \( \tau \) measures the proper time along the world line. The key equations governing the full structure of the spacetime are derived from the Ricci and the once and twice contracted Bianchi identities applied to the 4-velocity vector \( \mathbf{u} \). This splitting uniquely defines two projection tensors

\[
U^a_b = -u^a u_b \quad \Rightarrow \quad U^a_c U^c_b = U^a_b, \quad U^a_a = 1, \quad U_{ab} u^b = u_a, \tag{2}
\]

\[
h_{ab} = g_{ab} + u_a u_b \quad \Rightarrow \quad h^a_c h^c_b = h^a_b, \quad h^a_a = 3, \quad h_{ab} u^a = 0, \tag{3}
\]

which project along and orthogonal to the 4-velocity \( u^a \). We define two projected covariant derivatives, the convective time derivative along \( u^a \) and the spatially projected covariant derivative

\[
\dot{Q}^{a;b}_{c...d} \equiv u^c \nabla_c Q^{a;b}_{c...d} \quad \text{and} \quad D_c Q^{a;b}_{c...d} \equiv h^{a}_{p...q} h^{b}_{r...s} h^{c}_{d...e} \nabla_f Q^{p;q...r...s}_{f...g}, \tag{4}
\]

respectively. The basic equations are then characterized by the irreducible parts of the first covariant derivative of \( u_a \)

\[
\nabla_a u_b = -u_a A_b + D_a u_b = -u_a A_b + \frac{1}{3} h_{ab} + \sigma_{ab} + \omega_{ab}, \tag{5}
\]

where \( A_b = u^a \nabla_a u_b \) is the relativistic acceleration vector representing the effect of inertial forces on the fluid; \( D_a u^a = \Theta \) is the rate of volume expansion; \( \sigma_{ab} = D_a u_b \) is the symmetric trace-free rate of shear tensor, describing the rate of distortion of the fluid flow; \( \omega_{ab} = D_{[a} u_{b]} \) is the antisymmetric vorticity tensor, describing the rigid rotation of the fluid relative to a non-rotating frame.

### B. FLRW background

We choose as our background the FLRW models, which are spatially homogeneous and isotropic. Thus, relative to the congruence \( u_a \), the kinematical variables have to be locally isotropic, which implies the vanishing of the 4-acceleration \( u_a = 0 \), the rate of shear \( \sigma_{ab} = 0 \) and the vorticity vector \( \omega_a = 0 \). Spatial homogeneity implies that the spatial gradients of the energy density \( \mu \), pressure \( p \), and the expansion \( \Theta \) vanish, i.e \( D_a \mu = D_a p = D_a \Theta = 0 \). Moreover, the FLRW spacetime is characterized by a perfect fluid matter tensor, i.e \( \pi = \bar{\pi}_a = 0 \). These restrictions imply that the spacetime is conformally flat, i.e the electric and magnetic parts of the Weyl tensor vanish, \( E_{ab} = H_{ab} = 0 \). This leads to the key background equations, the energy conservation equation

\[
\dot{\mu} = -(1 + w) \Theta \mu, \tag{6}
\]

the Raychaudhuri equation

\[
\dot{\Theta} = -\frac{1}{3} \Theta^2 - \frac{1}{2} \mu (1 + 3 w) + \Lambda, \tag{7}
\]

where \( w = p/\mu \) and the Friedmann equation

\[
\mu + \Lambda = \frac{1}{3} \Theta^2 + \frac{3 K}{a^2}. \tag{8}
\]

### III. PERTURBATIVE FRAMEWORK

As already mentioned, a FLRW spacetime cannot readily host magnetic fields, as their anisotropic stresses \( \Pi_{ab} = \dot{B}_a \dot{B}_b \neq 0 \) will break the isotropy. We thus treat the background magnetic field \( B_a \) as a first order perturbation to the isotropic spacetime. This lends the energy density, the isotropic and anisotropic pressure of the field to second order in perturbation theory.

We then proceed by adopting a two parameter perturbative framework \cite{28, 32}. Fundamentally, this consists of separately parametrizing the gravitational and Maxwell field perturbations in two expansion parameters \( \epsilon_\phi \) and \( \epsilon_\beta \), representing the amplitudes of the gravitational and electromagnetic field perturbations, respectively \cite{18, 22, 24}. Using this parametrization, any quantity \( Q^{a...b}_{c...d} \) in the physical spacetime can be expanded in the form,

\[
Q^{a...b}_{c...d} = \epsilon_{\phi}^{(0)} Q^{a...b}_{c...d}^{(0...0)} + \epsilon_{\phi}^{(1)} Q^{a...b}_{c...d}^{(0...1)} + \epsilon_{\beta}^{(0)} Q^{a...b}_{c...d}^{(1...0)} + \epsilon_{\beta}^{(1)} Q^{a...b}_{c...d}^{(1...1)} + O(\epsilon_\phi^2, \epsilon_\beta^2), \tag{9}
\]

where the first term on the right represents the background term; the first and second terms represent the first order gravitational and electromagnetic perturbations respectively; the fourth term represents the non-linear coupling we're
looking to investigate; the higher order terms represent self-coupling terms of order $\epsilon^m_g$ and $\epsilon^n_B$, $m, n \geq 2$. In general, terms describing the coupling will be of the form $\epsilon^m_g \epsilon^n_B$, where, in this work, we restrict the perturbative order to $O(\epsilon^m_g \epsilon^n_B)$ and therefore neglect terms of order $O(\epsilon^m_g \epsilon^2_B)$, $O(\epsilon^2_B \epsilon^n_B)$ and higher, resulting from the self-coupling of the fields; this includes gravitational couplings with the magnetic anisotropy $\Pi_{ab} = -\tilde{B}_{(a} \tilde{B}_{b)}$, leading to $O(\epsilon^2_g \epsilon^n_B)$ terms. We will generally refer to quantities of order $O(\epsilon^m_g \epsilon^n_B)$ simply as non-linear and reserve the designation ‘second order’ for terms that are of order $\epsilon^2_g$ and $\epsilon^2_B$. As in [18, 22, 23], one can visualize this framework as a hierarchy of spacetimes to label the different perturbative orders.

We make the common assumption in the literature that the perturbed spacetimes have the same manifold as the background spacetime i.e. we consider the perturbations as fields propagating on the background spacetime [32, 33]. In this treatment, therefore, we restrict the possibility that the perturbations may alter the differential structure of the background manifold and so we neglect issues of backreaction.

We’re also interested in studying this coupling in a gauge-invariant manner. The gauge problem in relativistic perturbation theory has been dealt with in the literature, see for example [32, 34–37]. The Stewart & Walker Lemma [35] serves as a basis for the generalization of gauge invariance to arbitrary order [32, 36]. It follows that a quantity $\mathcal{Q}$ is gauge invariant at order $O(\epsilon^m_g \epsilon^n_B)$ if and only if $\mathcal{Q}^{(1)}$ and its perturbations of order lower than $O(\epsilon^m_g \epsilon^n_B)$ are either vanishing, or a constant scalar or a combination of Kronecker deltas with constant coefficients [28, 32].

Since the interaction terms are of order $O(\epsilon^m_g \epsilon^n_B)$ we have that the induced magnetic field $\tilde{B}_a$ will be of the same order; we also assume that the electric field $E_a$ will be of the same order as the induced magnetic field. Clearly $\tilde{B}_a$ does not satisfy the criteria for gauge invariance at $O(\epsilon^m_g \epsilon^n_B)$ since it is neither vanishing nor a constant scalar at $O(\epsilon^m_g \epsilon^n_B)$. To this end, we make use of the same auxiliary variable $\beta_{\alpha} = \tilde{B}_a + \frac{2}{3} \tilde{\Theta} \tilde{B}_a$ identified in [18, 22, 29]. We do not however integrate $\beta_{\alpha}$ to recover the gauge-dependent magnetic field, but treat it as the fundamental variable whose deviation from zero quantifies deviation from the adiabatic decay of the magnetic field.

IV. THE EINSTEIN-MAXWELL SYSTEM

The Einstein-Maxwell equations [10] contain terms that couple the electromagnetic fields to the gravitational fields. These can be written at $O(\epsilon^m_g \epsilon^n_B)$ by discarding higher order terms. This results in the two propagation equations,

\begin{align}
\dot{\tilde{B}}_{(a)} + \frac{2}{3} \Theta B_a &= \sigma_{ab} \tilde{B}^b - \text{curl } E_a, \\
\dot{\tilde{E}}_{(a)} + \frac{2}{3} \Theta E_a &= \text{curl } B_a + \epsilon_{abc} A^b \tilde{B}^c - J_a,
\end{align}

subject to the constraints, $D_a E^a = 0 = D_a B^a$. Following [38] we make the following comments: (i) The magnetic field $\tilde{B}_a$ appearing in the equations [13] and [14] multiplied by the gravitational variables should not be the same as the $B_a$ appearing alone. The variable $B^a$ is a mixture of linear and non-linear quantities (the seed magnetic field and the induced field) while the terms involving $\tilde{B}^a$ are a product of first order quantities. One has to keep this in mind when integrating the equations. (ii) The system is not gauge-invariant as already mentioned in §III. This can be attributed to the mixture of linear and non-linear terms in the system. In the covariant approach to perturbation theory, the solution of perturbed differential operators is never sought, one can get around this by making sure that the differential operators involved operate on quantities of the corresponding perturbative order.

In an attempt to cast it in a consistent and gauge invariant manner, we introduce the following non-linear variables:

The fundamental variable $\beta_{\alpha}$ measuring deviation from adiabatic decay, $I_a$ describing the interaction with shear distortions and $\xi_a$ describing interaction with density perturbations. These are defined as,

\begin{align}
\beta_{\alpha} &= \dot{\tilde{B}}_{(a)} + \frac{2}{3} \Theta B_a, \quad I_a = \sigma_{ab} \tilde{B}^b \quad \text{and} \quad \xi_a = \epsilon_{abc} A^b \tilde{B}^c
\end{align}

and results in the following system,

\begin{align}
\beta_{\alpha} &= I_a - \xi_a, \\
\dot{\tilde{E}}_{(a)} + \frac{2}{3} \Theta E_a &= \mathcal{R}_a + \xi_a - J_a,
\end{align}

where we have written $\text{curl } E_a = \xi_a$ and $\text{curl } B_a = \mathcal{R}_a$ for brevity.
V. THE LINEAR EQUATIONS

A. The linear magnetic field: $O(\epsilon_B)$

We treat the seed magnetic field as a first order perturbation to the spacetime. The seed field may have its origins in inflation or other mechanisms based on string cosmology, in which electromagnetic vacuum fluctuations are amplified due to a dynamical dilaton or an inflaton field [15]. We assume that at order inflation or other mechanisms based on string cosmology, in which electromagnetic vacuum fluctuations are amplified due to a dynamical dilaton or an inflaton field [15]. We assume that at order $O(\epsilon_B)$ the electric fields are small compared to the magnetic fields, i.e. $E^2 \ll B^2$. Thus, in the absence of diffusive losses or amplification, the induction equation [15] takes the frozen-in form,

$$\dot{\hat{B}}_{(a)} + \frac{2}{3} \Theta \hat{B}_a = 0 \ ,$$  

regardless of the equation of state or plasma properties of the cosmic fluid. It follows then that the magnetic field decays adiabatically as $\hat{B}_a \propto a^{-2}$, where $a$ is the cosmological scale factor. This adiabatic decay arises from the expansion of the Universe which conformally dilutes the field lines due to flux conservation. The frozen-in condition [15] does not discriminate between homogeneous ($D_a \hat{B}_b = 0$) and inhomogeneous ($D_a \hat{B}_b \neq 0$) magnetic fields. For an inhomogeneous field the spatial gradients of the seed magnetic field $D_a \hat{B}_b$ are of the same order as $\hat{B}_a$ and evolve as $D_a \hat{B}_a \propto a^{-3}$.

B. Gravitational perturbations: $O(\epsilon_g)$

The Weyl tensor $C_{abcd}$ represents the free gravitational field, enabling gravitational action at a distance. In analogy with splitting the Maxwell field tensor $F_{ab}$ into a magnetic and an electric field, $C_{abcd}$ can be split covariantly into a ‘magnetic’ part $H_{ab} = \frac{1}{2} \epsilon_{abc} C^{cde} u^e$ and an ‘electric’ part $E_{ab} = C_{abcd} u^c u^d$. The electric part of the Weyl tensor describes tidal effects, akin to the tidal tensor associated with the Newtonian potential, while the magnetic part describes the propagation of gravitational radiation. The Weyl tensor vanishes in the conformally flat FLRW spacetime and so $E_{ab}$ and $H_{ab}$ are covariant first order gauge invariant (FOGI) quantities in the Weyl curvature. We also define the FOGI variables $X_a = a D_a \mu$ and $Z = a D_a \Theta$ to characterize density perturbations. Now, the system governing gravitational perturbations is given by the following propagation equations [67],

$$\dot{\sigma}_{(ab)} + \frac{2}{3} \Theta \sigma_{ab} = D_{(a} A_{b)} - E_{ab} \ ,$$

$$\dot{H}_{(ab)} + \Theta H_{ab} = -\text{curl} \ E_{ab} \ ,$$

$$\dot{X}_{(a)} - \Theta w X_a = - (1 + w) Z_a \ ,$$

$$\dot{Z}_{(a)} + \frac{2}{3} \Theta Z_a = - \frac{1}{2} \mu X_a - \frac{w}{3(1 + w)} \left( \frac{1}{3} H^2 + \mu + \Lambda \right) X_a - \frac{w}{1 + w} D^2 X_a \ .$$

In addition to the propagation equations above, the following constraints have to be satisfied,

$$a D^c \sigma_{bc} = \frac{2}{3} Z_b \ , \quad a D^c E_{bc} = \frac{1}{3} \mu X_b \quad \text{and} \quad H_{ab} = \text{curl} \ \sigma_{ab} \ ,$$

where we have set the vorticity to zero ($\omega_a = 0$), see also [38]. Note that at first order in gravitational perturbations, the only source of vector modes is the vorticity $\omega_a$; since, we neglect the effects of vorticity, $\omega_a = 0$, all the vector modes vanish. The shear tensor $\sigma_{ab}$ can then be irreducibly split into scalar and tensor contributions as [59]

$$\sigma_{ab} = \sigma_{ab}^s + \sigma_{ab}^t \quad \text{where} \quad \text{curl} \ \sigma_{ab}^s = 0 \ , \quad \text{and} \quad D^a \sigma_{ab}^t = 0 \ .$$

The pure tensor modes can be used to characterize gravitational waves [40]. The scalar part of the shear couples to density perturbations and is related to the clumping of matter via the constraints [24]. By differentiating [16] and using [18] and one of the constraints [21] to substitute for $E_{ab}$ and $H_{ab}$, one arrives at a forced wave equation for the shear,

$$\ddot{\sigma}_{(ab)} - D^2 \sigma_{ab} + \frac{5}{3} \Theta \dot{\sigma}_{(ab)} + \left[ \frac{1}{9} \Theta^2 + \frac{1}{6} \mu - \frac{3}{2} p + \frac{5}{3} \Lambda \right] \sigma_{ab} = - \frac{w}{a^2 (1 + w)} \left[ X_{ab} + \frac{1}{3} \Theta X_{ab} \right] \ ,$$
Here we give wave equations for the induced Electric field.

One can start from \[19\] and \[20\] to write a wave equation for \( \mathcal{X}_a \) then taking the comoving spatial gradient of the resulting wave equation will yield the following,

\[
\ddot{\mathcal{X}}_{ab} - wD^2\mathcal{X}_{ab} - \left( w - \frac{2}{3} \right) \Theta \dot{\mathcal{X}}_{ab} + \frac{1}{2} \mu(3w + 1)(w - 1)\mathcal{X}_{ab} - 2w\Lambda \mathcal{X}_{ab} = 0 .
\]

In including scalar perturbations, we have explicitly coupled the shear tensor to density perturbations. This shows that density gradients source distortions in the Weyl curvature and vice versa. Hence, knowing the shear allows one to compute density gradients and knowing density gradients one can compute the scalar part of the shear \[41\].

VI. THE INTERACTION: \( \mathcal{O}(\epsilon_\theta \epsilon_\beta) \)

The Maxwell fields couple to Weyl curvature through the shear term and density perturbations through the acceleration terms and the non-linear identity \[23\]. In the case of pure tensor modes in the shear tensor, the interaction variable \( I_a = \sigma_{ab}^\mu \tilde{B}^\mu \) was shown to satisfy a closed wave equation, for both a homogeneous \[18\] and an inhomogeneous \[22\] seed field \( \tilde{B}_a \). Here, we include contributions from scalar perturbations in the shear, which give rise to source terms due to coupling with density perturbations. In this case \( I_a \) satisfies a forced wave equation,

\[
\ddot{I}_a - D^2I_a + 3\Theta\dot{I}_a + \left[ \frac{13}{9} \Theta^2 - \frac{1}{6} \mu - \frac{5}{2} \mu w + \frac{7}{3} \Lambda \right] I_a = C^I_a ,
\]

where the forcing term \( C^I_a \) is given by,

\[
C^I_a = -\frac{w}{a^2(1+w)} \left( \dot{S}_{(a)} + \Theta S_a \right) .
\]

To close the above system, we give the companion wave equation for \( S_a = a\tilde{B}^\mu D_{(a}\mathcal{X}_{b)} \) as,

\[
\ddot{S}_a - w D^2 S_a + (2 - w) \Theta \dot{S}_a + \left[ \frac{2}{3} (1 - w)(\Lambda + \Theta^2) + \frac{1}{6} \mu (1 + 3w) (3w - 5) \right] S_a = 0 .
\]

We note, for later convenience (§ VIII B) that the forcing term \( C^I_a = 0 \) in a matter dominated universe \( (w = 0) \) i.e \( I_a \) decouples from \( S_a \) when \( w = 0 \).

VII. INDUCTION OF EM FIELDS

We introduce non-linear gravitationally induced ‘effective current’ terms \( \mathcal{C}_a^E \), \( \mathcal{C}_a^\sigma \) and \( \mathcal{C}_a^I \) which are made up of the coupling between density and gravitational wave perturbations; these will act as driving forces of the induced Maxwell fields.

A. The Electric field

We show how the coupling of gravitational perturbations with the seed magnetic field can induce Electric fields. Here we give wave equations for the induced Electric field \( E_a \) and its rotation \( \phi_a \). In deriving the wave equation for \( E_a \), we differentiate \[14\] and equate the result to the non-linear identity,

\[
(\text{curl } B_a) = \text{curl } \beta_a - \Theta \text{ curl } B_a + H_{ab} \tilde{B}^b + \frac{1}{3a(1 + w)} \epsilon_{abc} \tilde{B}^b \left( \Theta w \mathcal{X}^c - 2 \mathcal{X}^c \right) ,
\]

obtained from the commutation relations (Appendix A 3) and we have used Equation \[19\] to rewrite the acceleration terms. The resulting wave equation is found to be,

\[
\ddot{E}_{(a)} - D^2 E_a + \frac{5}{3} \Theta \dot{E}_a + \left[ \frac{2}{9} \Theta^2 + \frac{1}{3} \mu (1 - 3w) + \frac{4}{3} \Lambda \right] E_a = C^E_a ,
\]
where $C^E_a$ is a gravitationally induced source term given by,

$$C^E_a = \text{curl} \, I_a + H_{ab} \hat{B}^b + \frac{1}{a(1+w)} \epsilon_{abc} \left( \left( w - \frac{2}{3} \right) (\hat{B}^b X^c) + \Theta \left( w - \frac{4}{9} \right) \hat{B}^b X^c \right) - \Theta J_a - \dot{J}_a, \tag{30}$$

and $J_a$ is the 3-current. The terms involving $\epsilon_{abc}$ in $C^E_a$ vanish when the magnetic field $\hat{B}^b$ is parallel to the fractional density gradient $X^a$. Taking the curl of (29) results in the equation governing the rotation of $E_a,$

$$\dot{\theta}_a - D^2 \theta_a + \frac{7}{3} \Theta \dot{\theta}_a + \left[ \frac{7}{9} \Theta^2 + \frac{1}{6} \left( 1 - 9 w \right) + \frac{5}{3} \Lambda \right] \theta_a = C^E_a, \tag{31}$$

where the source term $C^E_a = \text{curl} \, C^E_a$ is given by,

$$C^E_a = - \left( \text{curl} \, J_a \right) - \frac{4}{3} \Theta \text{curl} \, J_a + 2 D^b D_{[a} I_b] + \epsilon_{acd} \hat{B}^c D^d H^{db} \tag{32}$$

B. The Magnetic field

As already mentioned, the induced magnetic field will be characterized via the variable $\beta_a = \hat{B}_a + \frac{2}{3} \Theta B_a$. On using 13, 25 and 31 one can write a second-order equation governing the evolution of the fundamental variable $\beta_a$. This can be written in either of two forms: in terms of $I_a$ or $\dot{\theta}_a$, corresponding to using 13 as a constraint to either of 31 or 25 respectively. Recall that both $I_a$ and $\dot{\theta}_a$ satisfy wave equations of the form $\mathcal{L}[I_a] = C^I_a$ and $\mathcal{L}[\dot{\theta}_a] = C^\dot{\theta}_a$, where the $C^I_a$'s are source terms.

Using covariant harmonics 41, one can already notice from 25 and 31 that the eigenfunctions used to harmonically decompose $I_a$ and $\dot{\theta}_a$ are not the same for a general perturbation. Consider the induction equation 13 and write it as $\beta_a = \sum_k (P_a I_{(k)} - Q_a \dot{\theta}_{(k)}), \tag{33}$ where $P_a$ and $Q_a$ are distinct eigenfunctions of the Laplace-Beltrami operator, i.e $P_a \neq Q_a$. For the separation of variables technique to work for $\beta_a$, one must eliminate either $I_a = P_a I_{(k)}$, along with its source terms $C^I_a$ or $\dot{\theta}_a = Q_a \dot{\theta}_{(k)}$ along with its source terms $C^\dot{\theta}_a$. In this way, $\beta_a$ can then be expanded in terms of one set of complete eigenfunctions. This presents a problem: since both $I_a$ and $\dot{\theta}_a$ are coupled to source terms $C^I_a$ and $C^\dot{\theta}_a$ respectively at second-order, both $C^I_a$ and $C^\dot{\theta}_a$ will still couple to the $\beta_a$ equation at this order, thereby introducing the differing set of eigenfunctions $P_a$ and $Q_a$. A similar problem arose in 12, due to the inclusion of a vorticity term.

It is possible to do away with $C^I_a$ in equation 25 by requiring that $w = 0$ and this alleviates the problem 69. We shall then henceforth restrict to the pressureless dust $(w = 0)$ case and write the $\beta_a$ wave equation in terms of $\dot{\theta}_a$.

$$\ddot{\beta}_a - D^2 \beta_a + 3 \Theta \dot{\beta}_a + \left[ \frac{13}{9} \Theta^2 - \frac{1}{6} \mu + \frac{7}{3} \Lambda \right] \beta_a = C^\beta_a \tag{33}$$

where,

$$C^\beta_a = - \frac{2}{3} \Theta \dot{\theta}_a + \left[ - \frac{2}{3} \Theta^2 + \frac{1}{3} \mu - \frac{2}{3} \Lambda \right] \theta_a + (\text{curl} \, J_a) + \frac{4}{3} \Theta \text{curl} \, J_a - 2 D^b D_{[a} I_b] - \epsilon_{acd} \hat{B}^c D^d H^{db} \tag{34}$$

Note that while we keep $S_a = a \hat{B}^b D_{(a} X_b)$ distinct from $a \hat{B}_{(a} D^b X_b)$ in real space, their evolution equations can be made equivalent in harmonic space by a suitable choice of eigenfunctions 71. We shall thus write $S_{(k)}$ in place of $\hat{B}_{(a)} X_{(k)}$ to avoid introducing another letter to denote the latter. This should not lead to any ambiguities.

C. The Electric Current

1. Limiting cases: poor and perfect conductivity

To close the above system, one needs to take care of the current term $J_a$ appearing in 30, 32 and 33. This term depends on the electrical properties of the medium. It is given in terms of the Electric field $E_a$ via Ohm’s law,

$$J_a = \zeta E_a, \tag{35}$$
where $\zeta$ is the electrical conductivity of the medium. In this section, we consider only the limiting cases of very high ($\zeta \rightarrow \infty$) and very poor conductivity ($\zeta \rightarrow 0$). Under the assumption of poor conductivity, the currents vanish $J_a = 0$, despite the presence of a non-zero electric field. In this case, one solves equations 29, 31 and 33, with the current $\varsigma$ where

$$J = \frac{\mu e v_a^2 + \mu_i v_i^2}{\mu_e + \mu_i},$$

and equations 29 and 31 are no longer relevant. One can verify that using this relation reduces equation 33 to

$$\beta_a = D^2 \beta_a + \frac{13}{9} \Theta^2 - \frac{1}{6} \mu + \frac{7}{3} \Lambda \right] \beta_a = D^2 \beta_a + \frac{13}{9} \Theta^2 - \frac{1}{2} \mu - \Lambda \right] \beta_a.$$

Substituting (36) into (33) results in

$$\beta_a = \frac{2 D^2 D_a I_b}{a^2} + \frac{2 a}{a^2} \left[ \frac{1}{9} \Theta \left( \beta_a + 3 \zeta \beta_a \right) \right] \beta_a = D^2 \beta_a + \frac{13}{9} \Theta^2 - \frac{1}{6} \mu + \frac{7}{3} \Lambda \right] \beta_a.$$
where, \( n_e \) is the density of free electrons, \( e \) is the electric charge of an electron, \( m_e \) is the mass of an electron, \( n_\gamma \) is the density of photons and \( \sigma_T \) is the collision crosssection. For a perfect fluid, the ratio \( n_\gamma/n_e \) is constant, see [43] for example.

Assuming that Ohm’s law holds (Equation [35]), we may write the current terms in [34] as,

\[
\text{curl } J_a + \frac{4}{3} \Theta \text{curl } J_a = \zeta \dot{\epsilon}_a + \frac{4}{3} \Theta \dot{\epsilon}_a
\]

where we have assumed that spatial gradients of the conductivity may be neglected (\( \nabla \zeta \approx 0 \)) and that the conductivity is constant in time (\( \zeta \approx 0 \)). Substituting [43] in the wave equation [33] for \( \beta_a \) results in,

\[
\ddot{\beta}_a - \frac{2}{3} \beta_a + \frac{3}{2} \Theta \dot{\beta}_a + \left[ \frac{13}{9} \Theta^2 - \frac{1}{6} \mu + \frac{7}{3} \Lambda \right] \beta_a = C_\alpha^\beta
\]

where the source term \( C_\alpha^\beta \) is now given by,

\[
C_\alpha^\beta = \left( \frac{\zeta}{3} - \frac{2}{3} \right) \Theta \dot{\epsilon}_a + \left[ \left( \frac{2}{3} \Theta - 1 \right) \frac{2}{3} \Theta^2 + \frac{1}{3} \mu - \frac{2}{3} \Lambda \right] \epsilon_a - 2 D^b D_{[\alpha} I_{\beta]} - \epsilon_{acd} B_c D^c H^d b
\]

where we have assumed that \( \epsilon_a = 0 \) for poor conducting mediums and \( E_a = 0 \) for perfect conducting mediums) are no longer applicable in the case of finite conductivity. One then needs a proper model for the electric currents to ensure that the initial conditions for \( J_a \) and \( E_a \) are not chosen independently. There are several ways in which one can model electric currents, all resulting in terms of perturbative order \( \epsilon_a^2 \) see [43] for example. While these terms can be seamlessly accommodated in our framework, they have the undesirable effect of seeding magnetic fields. This will lead us away from the isolated effects of the amplification of an already existing field. Inclusion of such terms will therefore lead us to overestimate the effect of the amplification. With this in mind, we restrict to the limiting cases of VII C 1.

**VIII. THE INDUCED FIELDS**

We now treat separately the induction of electromagnetic fields due to interaction with scalar and tensor perturbations. To this end, we expand the perturbation variables in terms of a helicity basis (Appendix A 1). In addition, we use a unified time variable whose defining equation is \( \tau = \frac{\dot{a}}{a} H \) instead of proper time, to re-write the relevant equations [71]. We have to substitute for \( \mu, \Theta \) and \( a \), appearing in the perturbed equations, from the zeroth order equations. We restrict our treatment to zero cosmological constant \( \Lambda = 0 \) and flat spatial sections \( K = 0 \). Friedmann equation then reduces to \( \mu = \Theta^2 / 3 \), where \( \Theta \) is given by \( \Theta = 3 H / \tau \); the scale factor \( a \) evolves as \( a = a_0 \tau^{2/3} \).

**A. EM induction due to scalar perturbations**

In this case, the coupling of a seed field with gravitational perturbations is described by the variable \( I_a \) and \( S_a \); these variables become sources of electromagnetic fields.

- **Interaction terms:** Equations [26] and [27] for the interaction variables \( I_a \) and \( S_a \), respectively become,

\[
\frac{9}{4} I_{a(\ell)}'' + \frac{27}{2\tau^2} I_{a(\ell)}' + \frac{25}{2\tau^2} I_{a(\ell)} = 0, \tag{46a}
\]

\[
\frac{9}{4} S_{a(\ell)}'' + \frac{9}{7} S_{a(\ell)}' + \frac{7}{2\tau^2} S_{a(\ell)} = 0, \tag{46b}
\]

Note that since \( w = 0 \), the entire system has decoupled from \( a \hat{B}_a D_{[\alpha} I_{\beta]} \), however we still need an equation for \( S_{a(\ell)} \) because of the coupling with \( a \hat{B}_a D_{[\alpha} I_{\beta]} \) in Equations [82] and [83]. These interaction variables have the general solutions,

\[
I_{a(\ell)}(\tau) = C_1 \tau^{-10/3} + C_2 \tau^{-5/3} \quad \text{and} \quad S_{a(\ell)} = \frac{1}{5} C_3 \tau^{-7/3} + \frac{1}{5} C_4 \tau^{-2/3}, \tag{47}
\]

where the \( C_i \)’s are integration constants.
• EM fields: Equation 29 for the Electric field $E_a$ becomes,

$$\frac{9}{4} E''_a + \frac{15}{2\tau} E'_a + \left[ \left( \frac{\ell}{a_i H_1} \right)^2 \tau^{-4/3} + \frac{3}{2\tau^2} \right] E_a = \pm \frac{(k+n)}{3a_i H_1^2} I_a \tau^{-2/3} + \frac{1}{H_1} S'_a + \frac{4}{3H_1 \tau} S_a$$  \hspace{1cm} (48)

It is much easier to solve for $\beta(I)$ from the induction equation

$$\beta(I) = I_a \mp \frac{\ell}{a_i \tau^{4/3}} E_a$$  \hspace{1cm} (49)

once $I_a$ and $E_a$ are known, rather than from the wave equation 33.

• Interaction variable: Equation 25 for the interaction variable $I_a$ becomes,

$$\frac{9}{4} I''_a + \frac{27}{2\tau} I'_a + \left[ \left( \frac{\ell}{a_i H_1} \right)^2 \tau^{-4/3} + \frac{25}{2\tau^2} \right] I_a = 0 \ ,$$  \hspace{1cm} \hspace{1cm} (50)

with the general solution,

$$I_a(\tau) = \tau^{-5/2} \left[ C_1 J_1 \left( \frac{5}{2} \frac{\ell}{a_i H_1} \tau^{1/3} \right) + C_2 J_2 \left( \frac{5}{2} \frac{\ell}{a_i H_1} \tau^{1/3} \right) \right],$$  \hspace{1cm} \hspace{1cm} (51)

where $C_1$ and $C_2$ are integration constants, $J_1$ and $J_2$ are Bessel functions of the second kind.

• EM Fields: Equation 29 for the electric field variable $E_a$ becomes,

$$\frac{9}{4} E''_a + \frac{15}{2\tau} E'_a + \left[ \left( \frac{\ell}{a_i H_1} \right)^2 \tau^{-4/3} + \frac{3}{2\tau^2} \right] E_a = \pm \frac{(2k+n)}{H_1^2 a_i} I_a \tau^{-2/3}$$  \hspace{1cm} (52)

and we once again determine $\beta(I)$ from

$$\beta(I) = I_a \mp \frac{\ell}{a_i \tau^{2/3}} E_a$$  \hspace{1cm} (53)

instead of using the wave equation 33.

IX. INITIAL CONDITIONS

We need initial conditions in order to solve the equations in the previous section. The conditions are adapted as follows: for $\beta_a$ we invoke Maxwell’s equation 13

$$\dot{\beta}_a = \dot{I}_a = \dot{E}_a$$  \hspace{1cm} (54)

For the interaction variable $I_a$, we use the definition 12 and Equation 15

$$I_a = \sigma_{ab} \dot{B}^b \quad \dot{I}_a = \dot{\sigma}_{ab} \dot{B}^b + \sigma_{ab} \ddot{B}^b \quad \dot{\beta}_a = -\frac{2}{3} \Theta \dot{B}_a$$  \hspace{1cm} (55)

For the rotation of the Electric field $\dot{E}_a$, we use Maxwell’s equation 14 and the commutation relation A13 to get,

$$\dot{\dot{E}}_a = -\Theta \dot{E}_a + \mathcal{R}_{ab} \ddot{B}^b - D^2 \dot{B}_a$$  \hspace{1cm} (56)
where in this case \(B_a\) (without the tilde) is the induced magnetic field, and we have written the first order perturbed 3-ricci tensor \(\mathcal{R}_{ab}\) as \[25, 27\]

\[
\mathcal{R}_{ab} = -\dot{\sigma}_{(ab)} - \Theta \sigma_{ab}
\]  

We require that the gravitationally induced field variables \(E_a\) (and hence \(\sigma_a\)) and \(B_a\) be zero initially. This leads to the following initial conditions for the perturbation variables:

\[
\begin{align*}
I^i(t) &= \sigma^i(k) \tilde{B}^i(n) \\
\delta^i(t) &= 0 \\
\beta^i(t) &= \sigma^i(k) \tilde{B}^i(n)
\end{align*}
\]  

(58)

Following [21, 43, 10], we adopt the initial condition for the shear from \((\sigma/H_i) \sim 10^{-6}\). We choose the seed field to be \(\tilde{B}^i = 10^{-20}\) G, as typical of those produced around the recombination era [10].

X. RESULTS

Given the system of initial conditions [58] one can notice that the interaction variable \(I_a\) plays the fundamental role in the interaction process. If we set \(I_a = 0\) initially, then no amplification takes place. We show the time evolution \(I_a(\tau)\) in Figure 1 on a log-log scale. A noteworthy feature is the rapid decay of \(I_a\) for both scalars and tensors. Although the interaction with scalar perturbations decays slightly slower, it essentially follows the same trend as the interaction with gravitational waves. We are thus led to conclude that even including scalar perturbations in the interaction, we reach the same conclusion as [19] and [45] that there is no significant amplification of electromagnetic fields coming from the interaction.

![FIG. 1: Time evolution of the interaction variable in log-log axes. Note that for the interaction with scalars, the decay is slightly slower than for tensors.](image)

The effect of the gravitational perturbations on the interaction is thought to be largest at the point where the modes enter the horizon. This is clearly evident in Figures 2(a) and 2(b). A couple of features are worth noting from Figure 2(a). One is that the spectrum for the interaction variable mimics that of gravitational waves. It is also consistent with the fact that gravitational waves start oscillating at horizon crossing. This is to be expected since although for a spatially inhomogeneous magnetic field \(B_a\), the product \(I_i(t) = B_i(n)\sigma_i(k)\) becomes a convolution in Fourier space, \(I(k) = \sum_n B(n)\sigma(k - n)\), we have only considered the mode-mode coupling case, \(I(k) = B(k)\sigma(k)\).
FIG. 2: Plots of Power vs scale ($\ell$); we define the power as $P_\ell = |x(\ell)|^2$. (a): Power spectra of the magnetic field variable $\beta(\ell)$ (green, solid), and the interaction variable $I(\ell)$ (blue, dashed) at redshift $z = 0$ for the tensor case. (b): Power spectra of the magnetic field variable $\beta(\ell)$ (green, solid), and the interaction variable $I(\ell)$ (blue, dashed) at redshift $z = 0$ for the scalar case.

The power spectra for the case of interaction with scalars are not as interesting. There is no scale dependence on the interaction variable $I_\ell$, cf equation 46a. This is because the Laplacian term for scalar perturbations comes from the acceleration vector which is identically zero in the dust case $A = 0$.

It would be interesting to generalize our treatment to include the case of non-zero pressure. This will lead us to the radiation dominated era where one can incorporate photons in the plasma and can consider collisional effects as was done in [9, 10] for example. One could treat the interesting case of simultaneous generation and amplification of magnetic fields by coalescing these phenomenon.

XI. CONCLUSIONS

We have carried out an analysis of the coupling between gravitational perturbations with electromagnetic fields as a possible means for magnetic field amplification. This carries to completion the work began in [18] and [22]. In agreement with the work of [19] and [45] we argue that there is no significant amplification resulting from the interaction of magnetic field with gravitational waves. Even with the inclusion of density perturbations, the induced fields may still be orders of magnitude smaller. This justifies the perturbative treatment and our neglect of backreaction.

The induction of electromagnetic fields due to the interaction of a test magnetic field with gravitational waves was studied in [20] using the weak-field approximation. We included this study here treating the background magnetic field as a first order perturbation and recovered similar results. This shows that there is no fundamental difference between the two approaches, apart from a labeling of spacetimes, which should not affect physical results. We also extended this study by using a proper non-linear perturbative framework. This framework was applied in [18], but an erroneous argument there led to the neglect of the rotation of the Electric field, thus restricting the study to perfectly conducting environments. This was refuted in [52]. In fact, upon inspection of [58] one can conclude that even if one initially sets the rotation of the Electric field to zero, $\delta_\ell = 0$ there are non-zero terms on the right hand side of the initial conditions for $\delta$ that will seed a non-zero $\delta$. We also carry to completion the work in [22] by doing a proper extraction of the scalar and tensor modes and numerical integrations. In terms of the conductivity of the cosmic medium, [23] restricted their study to poor conducting mediums, [18] to perfectly conducting mediums and [22] treated the MHD approximation. We carried our analysis for all three cases. We find that for tensor perturbations, the ideal MHD approximation is just the same as the perfect conductivity assumption of the fluid treatment. For scalar perturbations, we find an additional source term in the induced field (compared with perfectly conducting environments) due to the coupling of the seed field with scalar velocity perturbations. The current term $J_\ell$ was neglected at all orders in [18], in an attempt presumably to uphold the background magnetic field’s homogeneity condition $D_a \tilde{B}_b = 0$. However, this is not necessary since introducing the current term at the non-linear order does
not break the condition $D_a \tilde{B}_b = 0$. Also, one cannot consistently invoke Ohm’s law for poor and perfect conducting environments without a current term. In \cite{22}, an inhomogeneous seed field was assumed thereby requiring a first order current $\mathcal{J}^a = \rho_e v_0^a + \rho_i v_0^i = -\epsilon(n_e v_0^e - n_i v_0^i)$ to uphold the condition $D_a \tilde{B}_b \neq 0$. However, after decoupling (which is the era considered there), Thompson scattering is no longer efficient. Thus electrons and ions are tightly coupled by coulomb scattering at first order. Their velocity fields are therefore equal as they form a perfectly coupled baryon fluid \cite{50,51}. There can be therefore no currents generated at this order and the condition $\text{curl} \tilde{B}_a = \mathcal{J}_a$ will render the seed field homogeneous.

Both \cite{18} and \cite{22} integrate $\beta_a$ to recover the amplified magnetic field, after specifying a frame $u^a$. While this takes into account the frame dependence of the magnetic field $B_a$, it invalidates gauge invariance as the recovered $B_a$ remains gauge dependent and takes the same value and form as it would have without the introduction of $\beta_a$. This is already pointed out in \cite{52}. See also \cite{53} and \cite{54}. We do not integrate $\beta_a$ but simply note that one can assign a physical meaning to the magnetic field variable $\beta_a$ by noting that $\beta_a = 0$ describes the background adiabatic decay of the fields. Any deviation from $\beta_a = 0$ would then imply amplification of the background field. Moreover, $\beta_a$ is a linear combination of terms that source magnetic fields through the induction equation \cite{13}. Thus we can estimate the relative importance of each source term through $\beta_a$ without having to integrate it to recover the gauge-dependent $B^a$. For example, we see from Figure 2(a) that the rotation of the electric field dominates at small scales compared to the interaction term. Observations of cosmological magnetic fields are difficult enough as it is, a new cosmological observable would lead to better understanding of studies in magnetic fields. While $\beta_a$ may not be that quantity, it does arise naturally from Maxwell’s equations.

Also, one can readily write our key equations in terms of metric variables by adoption of a suitable tetrad as was done in \cite{5}.

Mechanisms that seek to generate magnetic fields, relying on non-linear perturbation theory are attractive for several reasons \cite{55}. Among these is that they can easily blend in with known physics as they become relevant around the recombination era. This makes it possible to quantitatively evaluate the generated fields using CMB constraints. Progress in non-linear perturbation theory will allow us to investigate these non-linear effects in a manner that is free of spurious gauge modes \cite{38,56}.

\appendix

\section{Harmonic Splitting}

\subsection{Harmonic Splitting}

It is standard to decompose the perturbed variables harmonically in Fourier space; separating out the time and space variations \cite{41,58,59}. The idea is to expand the quantities in terms of eigenfunctions of the Laplace-Beltrami operator. To this end, we introduce the helicity basis vectors $e^{(-)}$, $e^{(0)}$ and $e^{(+)}$ defined by

\begin{equation}
\begin{aligned}
e_a^{(z)} &= -\frac{i}{\sqrt{2}} (e_a^1 \pm i e_a^2) \\
\text{where} \ (e^1, e^2, \hat{k}) \ \text{form a right-handed orthonormal system with} \ e_2 = \hat{k} \times e_1 \ \text{and we align} \ e^a \ \text{with} \ \hat{k}.
\end{aligned}
\end{equation}

Using this basis, the scalar harmonic functions are given by,

\begin{equation}
\begin{aligned}
Q^{(0)} &= e^{ik_j x^j}.
\end{aligned}
\end{equation}

Scalar type components of vectors and tensors are expanded in terms of harmonic functions defined from $Q^{(0)}$ as follows,

\begin{equation}
\begin{aligned}
Q^{(0)}_{a} &= -\frac{a}{k} D_a Q^{(0)} = a \hat{k}_a e^{ik_j x^j}, \ \text{(A3)} \\
Q^{(0)}_{ab} &= \frac{a^2}{k^2} D_a D_b Q^{(0)} = -a^2 \left( \hat{k}_a \hat{k}_b - \frac{1}{3} \delta_{ab} \right) e^{ik_j x^j}. \ \text{(A4)}
\end{aligned}
\end{equation}
Vector harmonics are given by
\[ Q^{(\pm)}_a = e^{(\pm)}_a Q^{(0)}, \quad (A5) \]
\[ Q^{(\pm)}_{ab} = -\frac{a}{k} D_{(a}e^{(\pm)}_{b)} Q^{(0)} + a i \hat{k}_{(a} e^{(\pm)}_{b)} e^{ikx^i}. \quad (A6) \]

While tensor harmonics are defined as,
\[ Q^{(\pm)}_{ab} = \sqrt{\frac{3}{2}} e^{(\pm)}_a e^{(\pm)}_b Q^{(0)}. \quad (A7) \]

2. Maxwell’s Equations

The Maxwell field tensor \( F_{ab} \) decomposes relative to the fundamental observer as,
\[ F_{ab} = 2u_a E_b + \epsilon_{abc} B_c, \quad (A8) \]
where \( E_a = F_{ab} u^b \) and \( B_a = \frac{1}{2} \epsilon_{abc} F^{bc} \) are respectively the Electric and Magnetic field as measured by the fundamental observer moving with 4-velocity \( u^a \). These are 3-vectors on the spacelike hypersurface, \( E_a u^a = 0 = B_a u^a \). The Maxwell’s equations are given by
\[ \nabla_a F_{bc} = 0 \quad \text{and} \quad \nabla^b F_{ab} = J_a, \quad (A9) \]
where \( J \) is the 4-current. These equations can be decomposed covariantly into the following \([25, 60, 61]\)
\[ \dot{E}_{(a)} - \text{curl} B_a = -\frac{2}{3} \Theta E_a + \sigma_{ab} E^b + \epsilon_{abc}(\mathcal{A}^b B^c + \omega^b E^c) - \mu_0 J_{(a)}, \quad (A10a) \]
\[ \dot{B}_{(a)} + \text{curl} E_a = -\frac{2}{3} \Theta B_a + \sigma_{ab} B^b + \epsilon_{abc}(\mathcal{A}^b E^c + \omega^b B^c), \quad (A10b) \]
\[ 0 = D_a E^a - 2\omega_a B^a - \frac{\rho_c}{\epsilon_0}, \quad (A10c) \]
\[ 0 = D_a B^a + 2\omega_a E^a. \quad (A10d) \]
The EM fields are solenoidal in the absence of gravitational vector perturbations.

3. Commutation Relations

\[ (\mathcal{D}_a f)_{\perp} = \mathcal{D}_a \hat{f} - \frac{1}{3} \Theta \mathcal{D}_a f + \hat{f} \mathcal{A}_a, \quad (A11) \]
\[ (\mathcal{D}_a V_b)_{\perp} = \mathcal{D}_a \hat{V}_b - \frac{1}{3} \Theta \mathcal{D}_a V_b - \sigma_{a}^{c} \mathcal{D}_c V_b + \epsilon_{bcde} V^d + A_a \hat{V}_b, \quad (A12) \]
\[ (\text{curl} V_a)_{\perp} = \text{curl} \hat{V}_a - \frac{1}{3} \Theta \text{curl} V_a - \epsilon_{abc} \sigma_{bd} \mathcal{D}_d V^c + H_{ab} V^b - \frac{1}{3} \Theta \epsilon_{abc} V^b \mathcal{A}_c, \quad (A13) \]
\[ \text{curl curl} S_{ab} = -D^2 S_{ab} + (\mu + \Lambda - \frac{1}{3} \Theta \mathcal{G}) S_{ab} + \frac{3}{2} D_{(a} D^c S_{b)c}. \quad (A14) \]

This is not a generic feature of all Friedmann universes however. It is possible to ‘preserve’ primordial magnetic fields in an open Friedmann universe; the hyperbolic geometry can slow down the adiabatic decay of the field leading to superadiabatic amplification [62, 63], see also [64].

For the purposes of this argument, we refer to perturbations of order $\epsilon g \epsilon ˜ B$ as second order, with evident misuse of terminology. In the rest of the work, we will refer to quantities of this order simply as non-linear and reserve the designation ‘second order’ to quantities of order $\epsilon^2 g$ and $\epsilon^2 B$.

Equation 16, is obtained from the Ricci identities applied to the whole spacetime; 17 and 18 are obtained from the once contracted Bianchi identities; 19 and 20 are obtained by taking spatial gradients of the energy conservation and Raychaudhuri equation, respectively.

In particular, for scalar perturbations, we expand $I_n$ as $I_n = ˜ B_n(\sigma(k) \bar{\tilde{H}}(n)(D_c D_b)Q^{(k)})$ and $C_n$ as $C_n = C_n^{(x)} D^c D_b Q^{(k)}$.; these are evidently not the same eigenfunctions. Implicitly, $C_n^{(y)}$ will be expanded in the same harmonics as $I_n$, and similarly for $E_n$ and $C_n^{(z)}$.

This is not to say that $w = 0$ is any more special than $w = 1/3$, we simply invoke it here to decouple 25 from the source terms; indeed, any other method to achieve this would suffice. As a matter of fact, when considering only tensor perturbations, 25 does not couple to any source terms, even for a general $w$. Moreover, when including vector perturbations, Equation 25 does couple to a source term $a^2 ˜ H_b D^c D_b Q$, even when $w = 0$.

In particular, expanding $a^2 ˜ H_b D^c D_b Q$ in terms of $a^2 \bar{\tilde{H}}(n)(D_c D_b)Q$ and $a^2 ˜ H_b D^c D_b Q$ will yield the same harmonic components $S_n^{(y)} \equiv ˜ B_n(\sigma(k) \bar{\tilde{H}}(n)(D_c D_b)Q)$ and $S_n^{(z)} \equiv a^2 ˜ H_b D^c D_b Q$ are eigenfunctions of the Laplace-Beltrami operator.

The subscript $i$ marks some initial time $\tau = 1$, see [18] for details.

Note that the Electric field $E_n$ and its curl $C_n$ are related by a factor of $\ell$ when expanded in terms of the helicity basis described in Appendix A. In particular $C_n = \pm (\ell/a_i) \tau^{-2/3} E(\pm) C_n^{(x)}$.
